The graphic on the cover, from Guo *et al.* (in this issue, pages 61–71), summarizes the authors' suggestion that future research should integrate multiomics data with clinical, imaging, genetic, and pathology data to advance our understanding of sex differences in Alzheimer's disease (AD). This proposed approach could be extended to psychiatric research more broadly, as evidenced by the papers throughout this special issue highlighting the advances and insights that have been generated through transcriptomic analyses into the sex differences in neuropsychiatric disorders.
